

PROGRAMMING FOR NON-PROGRAMMERS BOOTCAMP

Begin, introductions

10:00

Instructor Intro, class intro.

Students introduce themselves.

Intro to programming and the internet

10:30 - Lunch

High level overview of various programming languages and what they do.

Essential Terminology

Learning Objective: Learn the essential words and concepts that are used on a daily basis by engineers and project/product managers on the job.

Here are some words and concepts that will hopefully give you a more holistic view of the more technical aspects of the industry.

Define: Program

Discrete, highly logical and explicit instructions that are parsed and executed by a computer.

We call this set of human-readable instructions **source code**, or colloquially, a **computer program**.

Compilers can take this source code and transform it into **machine code**, a representation of the source that can be executed by the computer's **central processing unit** or **CPU**.

Not all programs are compiled though, some are **interpreted**. The difference is that compiled languages need a step where the source code is physically transformed into machine code. However, with an interpreted language, this additional step is **excluded** in favor of **parsing** and **executing** the source code directly when the program is run.

Speaking of source code, sometimes programmers, even ones acting on behalf of corporate giants like Apple, publish the source code for their programs. This is called **open source**.

How programs are written

All programs are composed with a collection of **fundamental** concepts that, when combined, can essentially dictate a wide variety of tasks a computer can perform.

Here are a collection of these most important concepts:

- **Declarations:** typically, we can store and retrieve data in our programs by associating them with intermediary values that we call **variables**
- **Expressions:** we use expressions to evaluate stuff. For example, **2 + 2** is an example of an expression that will **evaluate** a value, namely 4.
- **NOTE:** typically we can use expressions and declarations in tandem to perform complex tasks. For instance, we can reference a variable we declared in an expression to help us evaluate new values which can then be stored.
- **Statements:** statements will use expressions and declarations to alternate a program's **control flow**, which is essentially the order in which declarations, expressions, and other statements are executed.

Aside from these fundamental concepts, we also talk a lot about this idea of **algorithms**. An **algorithm** is simple a series of declarations, expressions, and statements that can be used over and over again to solve well defined problems of a certain type.

People tend to talk about algorithms like they are mysterious forces of nature, but I guarantee that you know a few algorithms yourself.

For example, we can implement an algorithm that converts temperature from **fahrenheit** to **celsius**. It would look something like this:

1. **Declare** $F = 32$;
2. **Expression** ($F - 32$) / 1.8;
3. **Declare** $C = \text{Evaluated}$ expression from **(2)**

This is a form of **pseudo** code where we define the steps a computer program — **any** — computer program can take to convert **fahrenheit** to **celsius**.

The beauty of programming is that all of it revolves around the same key set of concepts and ideas. For this reason, we do not need to specify any **particular programming language** when discussing the functional aspects of a program.

Define: Programming languages

A programming language is a series of **grammar** and **rules** that we can define towards writing source code.

Languages are effectively different approaches towards communicating the same ideas in programming. Essentially, we can communicate in say both **French** and **English**, what mainly differs is the structure of our sentences and the actual words and sounds themselves.

The **same analogy** can be made with programming languages.

Examples of programming languages

There are many. Way too many.

Here are some of the most popular ones, though.

1. **JavaScript**: this language is interpreted.
2. **Python**: this language is interpreted.
3. **Java**: this language is compiled
4. **Ruby**: this language is interpreted.
5. **C/C++**: this language is compiled.

These languages all build on the same concepts defined above; the main difference lies in **how** they are run (compiled vs interpreted) and also **how** they are used.

In general, anything programmable can be programmed in each of the languages defined above. However, some languages are better suited for certain tasks above others.

For example, to perform web programming on the front-end, you'll want to write JavaScript. This is because all browsers collectively support running javascript within it's environment.

What is web development?

The use of programming languages and concepts towards producing a system that listens to user requests over the internet and serves back HTML, CSS, and interaction code to the client.

What is the difference between a web site and web app

Web sites are more **static**. Think of them as sort of like interactive brochures. They typically don't hold any state and are usually just information.

A web app is more like an iOS or Android app. It holds state, does not refresh itself and in general **does something** vs **showing something**.

What are the stages of web development

Depends on the methodology used by team. Typically, there is a UX phase, a Design phase, a Development phase bundled with extensive QA. This was the process used in the consulting firm I used to work in.

For a startup, the process is similar, however there is a lot more room for iteration and testing out ideas by putting something up for users to use and deliver feedback.

What is the difference between front-end and back-end web development

Front end: Client side interactions and structure. This includes stuff like iOS apps and whatever you load in browser.

Back end: Server side, data storage and retrieval. Needs a client **of some sort** (not necessarily a browser) to work. Deals with storing and retrieving information.

Main Class Deliverable

In order to explore the core concepts of this class and achieve our learning objectives, we will recreate the **traditional resume template** for the web.

Key Requirements

- Template should resemble the typical resume.pdf we all maintain
- Template should use tasteful CSS3 styles to accentuate key pieces of information and design principles
- Template should work across all screens including (and specifically) mobile
- Template should be **printer friendly** and take up exactly one page when printed.

Here is an **example**.

HTML LESSON

Show them pop code and script ed sheet.

FRONT END CODE IS TOTALLY ON YOUR OWN MACHINE

Show them dev tools

look at dev tools in facebook

Go and change some stuff in the browser's rendered HTML.

YOU DO

- Go to a news website and have some fun.
- Make your uncle the king of Thailand. Change the election results. Add some digits to your bank account.
- Refresh the page and see your dreams melt away.

HTML BASICS

Create a folder on your desktop called `resume_html`

Drag it onto Atom in the dock or taskbar in windows.

Create a new file in there called `resume.html`

Before your browser even knows that it's supposed to roll with HTML, you have to tell it.

```
1 <!doctype html>
2 <!-- this is a comment that will show up in
   source code-->
3
4 <!-- Most users won't see this -->
5
6 <html>
7   <head>
8     <!--
9     the HEAD section of html does not have any
10    content
11    that the user can see
12    instead, we place things like:
13    page title
14    external css links
15    SEO keywords
16    here
17    -->
18    <meta charset="utf-8">
19    <title>My resume</title>
20  </head>
21  <body>
22    <!--
23
24    the BODY section will contain all the tags
25    that the user can _SEE_ and _INTERACT_ with
26    -->
27  </body>
28 </html>
```

<https://twitter.com/iamdeveloper/status/481859418137853952>

HTML is made of *elements*.

Each little thing is an element.

```
<!doctype html>
```

This tag tells the browser to read our HTML content as HTML5, the latest and greatest revision of the HTML spec. We MUST include it as the first thing on our .html files. I usually type it as all lower case, but it's common practice to also type as: <!DOCTYPE html>

This is the root tag. Basically, all other tags in your html file must live inside this tag. Note how on the bottom of the code snippet, we have a This is called closing a tag and we must close all tags that we open (with the exception of a few). If we do not do this, our HTML markup becomes invalid.

This section contains content that does not show the user things. Typically, we would expect to see things such as the page title, external links, and SEO tags here.

All the magic happens here. All the tags the user interacts with should live in this tag.

Comments and why they are so handy for programmers

```
1  <!--  
2   the h1 - or heading one - will have the most  
   important text on page  
3   by the old guard, we should really only have  
   one h1 per page  
4   -->  
5   <h1>Hello, Wrold</h1>
```

```
6
7  <h2>This is a h2</h2>
8
9  <h3>This is an h3</h3>
10
11 <h4>This is an h4</h4>
12
13 <h5>This is an h5</h5>
14
15 <h6>This is an h6</h6>
16
17 <!--
18  this is an inline element
19  unlike the block element, which is meant to
    provide structure
20  the inline element is interpreted as content
21  this means that will appear next to one
    another
22  -->
23 <strong>This is an inline element</strong>
24 <strong>This is another inline
    element</strong>
25
26 <!-- this is a block element so it will NOT be
    on the same line -->
27 <h1>Will this be on the same line?</h1>
28
29 <!--
30
31  differences between block elements and inline
    elements
32  block: takes up entire width of page unless
    otherwise told
33  (we don't know how yet)
34  we can impose dimensions on block elements
```

[illegible]

```
target="_blank">Hello, Wrold I'm ALSO a link,  
yo</a>
```

65

```
66 <em>This is an em</em>
```

67

```
68 <p>This is a paragraph.This is a  
paragraph.This is a paragraph.This is a  
paragraph.This is a paragraph.This is a  
paragraph.This is a paragraph.This is a  
paragraph.This is a paragraph.This is a  
paragraph.This is a paragraph.This is a  
paragraph.This is a paragraph.This is a  
paragraph.This is a paragraph.</p>
```

69

```
70 
```

```
71 <span>This is a kitten. S/he is cute.</span>
```

72

```
73 <ul>
```

```
74 <li>This is a list item <div></div></li>
```

```
75 <li>This is another list item</li>
```

```
76 <li>This is a third list item</li>
```

```
77 </ul>
```

78

```
79 <ol>
```

```
80 <li>This is an ordered list item</li>
```

```
81 <li>This is another ordered list item</li>
```

```
82 <li>This is a third ordered list item</li>
```

```
83 </ol>
```

84

```
85 <hr>
```

```
86 <p> wow look at that line
```

87

```
88 </p>
```

```
89  <div></div>
90
91  <span></span>
```

Show them PopCode

Assignment lab:

You now have everything you need to make a resume in HTML.

It's going to be all Times New Roman and stuff but it's important to get the practice into your very fingers.

Use your actual resume or generate nonsense text at Hipster Ipsum

<https://hipsum.co/>

After you are in good shape, we'll use some CSS to give these Crappy Times New Roman things style.

CSS!

CSS is code that tells the browser how to make things look. It's hella fast and powerful.

CSS Zen Garden

- Show inline styles and explain why they are the devil
- Show how to put it in a style tag
- Show how to link in a stylesheet relatively
- Show how to link in a Google font
- difference between block and inline elements

```
### CSS selectors and properties
```

selectors

- tag name
- id
- class
- mixture of the two
- child selector

Properties

- color
- font-family
- font-size
- width

- float
- height
- width
- font
- background image
- width percentage

show

Semantic HTML5 Tags

Here are some of the main tags that are supported.

SECTION: Represents a generic document or application section.

HEADER: Represents a group of introductory or navigational aids..

FOOTER: Represents a footer for a section and can contain information about the author, copyright information, et cetera.

NAV: Represents a section of the document intended for navigation.

MAIN: Defines the main content of a document.

ARTICLE: Represents an independent piece of content of a document, such as a blog entry or newspaper article

ASIDE: Represents a piece of content that is only slightly related to the rest of the page.

Exercise with the About me Code along

Final CSS:

```
1
2  h1, h2 {
3      font-family: 'Times New Roman'
4
5      color: #CFD11A;
6  }
7
8  p, li {
9      font-family: 'Times New Roman'
10 }
11
12 body {
13     background: url('../images/abstract-mosaic-
14         background.png') no-repeat center center fixed;
15     background-size: cover;
16 }
17
18 .wrapper {
19     width: 960px;
20     margin: 0 auto;
21 }
22
23 header, footer {
24     background: #595959;
25     color: #91C499;
26     padding: 15px 30px;
27     text-align: center;
```

```
27 }
28
29 header img {
30     width: 50%;
31     border-radius: 15px;
32 }
33
34 .main-content {
35     background: #808F85;
36     padding: 10px 0;
37     border-top: 2px solid #CFD11A;
38 }
39
40 .main-content ul {
41     list-style-type: none;
42     padding-left: 0;
43 }
44 .main-content ul li {
45     padding: 10px;
46     text-align: center;
47 }
48
49 a {
50     color: #CFD11A;
51     text-decoration: none;
52 }
53 .main-content p {
54     margin: 10px 40px;
55 }
56
57 #projects {
58     background: #808F85;
59     margin: 0 auto
60 }
61
```

```
62 .clearfix:after {
63     content: "";
64     display: table;
65     clear: both;
66 }
67
68 .project {
69     width: 30%;
70     display: inline-block;
71     background: #F2E9DC;
72     margin: 1.66%;
73     border-radius: 15px;
74     float: left;
75 }
76
77 .project h2 {
78     text-align: center;
79 }
80
81 .project img {
82     max-width: 100%;
83 }
```

DEPLOY TO THE WEB WITH GITHUB PAGES

Make sure that you have a Github.com account.

Brief review of git and GitHub. Show the commits to the actual class code repo.

<https://desktop.github.com/>

Create a repo on your desktop called .github.io

In finder, move index.html into that folder that was created.

Look in the github client to see what results.

Commit to master with a suitable commit message.

Publish.

Look at your github account

Go to .github.io in your browser.

Holy smokes!

Edit one line of index.html and commit/push.

Move the resume html in there as well. Repeat.

YOUR TURN

Move the styles files into the repo and publish to the web.

Congratulations :)

IF there is more time, introduce Semantic UI
